

CHAIN POKER GENESIS BY LAEV (peroqtdigo)

Monetary Settlement Engine

Official Technical Specification v1.2 - Corrected and Integration Audited

LCCP SEQ: 12 | PREV: 11 | SELF: 12 | NEXT: 13 | CLASS: CORE ENGINE | STATUS: INTEGRATION-READY

1. PURPOSE

The Monetary Settlement Engine (MSE) executes authorized monetary settlement operations. It does not determine poker outcomes, player membership, table lifecycle, wallet-instance lifecycle, or permission policy.

2. AUTHORITY BOUNDARY

The MSE is an execution authority, not a poker-rule, governance, membership, or wallet-lifecycle authority. It MUST NOT independently decide winners, entitlements, joins, seat release, disconnection consequences, or TABLE_WALLET_INSTANCE lifecycle. Financial operations reach the MSE through the protocol authorization path.

3. ENGINE RELATIONSHIPS

Poker Rules Engine: supplies the official poker result; does not execute money.

Requests and Permissions Engine: authorization boundary for financial operations; MSE does not replace it.

Table Wallet Engine: owns TABLE_WALLET_INSTANCE lifecycle and wallet-state authority.

Player Node Disconnection Management Engine: manages connection/removal/seat lifecycle; disconnection is not financial authorization.

Protocol Documentation Engine: documents and versions the MSE; does not control execution.

Table Creation Governance Engine: establishes table configuration, including settlement implementation.

4. TABLE_WALLET_INSTANCE

The MSE MUST NOT create, destroy, open, close, suspend, resume, or otherwise define TABLE_WALLET_INSTANCE lifecycle unless a future specification explicitly assigns such authority. The Table Wallet Engine remains lifecycle authority. MSE executes authorized operations through its wallet interface.

5. SETTLEMENT OPERATION LIFECYCLE

Settlement operation lifecycle is distinct from TABLE_WALLET_INSTANCE lifecycle. Conceptual states:

CREATED, AUTHORIZED, SUBMITTED, CONFIRMED, FAILED, and where required PENDING/UNKNOWN. A failed or uncertain settlement MUST NOT be represented as successful.

6. IDEMPOTENCY AND REPLAY

Every settlement instruction MUST have a unique operation identifier or equivalent idempotency key.

Replaying the same authorized instruction MUST NOT create an unintended second settlement. Evidence must permit duplicate detection.

7. INSTRUCTION INTEGRITY

The MSE MUST validate selected engine, asset, network, destination, amount, context, expiry and structural validity. It MUST reject malformed, incomplete, duplicated, expired, or non-executable instructions. It MUST NOT alter authorized economic entitlement merely to execute the operation.

8. DEFAULT BITCOIN IMPLEMENTATION

Bitcoin is the official default monetary asset. Bitcoin asset, network, settlement rail, payment channel and Layer-2 implementation are distinct concepts. The selected implementation must identify the applicable network and settlement mechanism.

9. MODULAR SETTLEMENT INTERFACE

A compatible settlement implementation must support authorized instruction intake, validation, execution/submission, result reporting, status/evidence reporting, and failure handling. Other assets or financial infrastructures may be integrated when they implement the required interface and table configuration permits them.

10. TABLE CREATION AND COMPATIBILITY

Settlement implementation is selected through table-creation governance and becomes part of official table configuration. A node must satisfy the selected implementation requirements before participating.

MSE does not conduct governance or independently authorize membership. Until a migration procedure is formally specified, the selected implementation governs the table lifecycle.

11. FUNDS AND SCOPE

The MSE operates through the wallet interface defined by the Table Wallet Engine. The previous universal claim that the table wallet is the sole source and destination of every monetary movement is removed.

External funding, withdrawal, channels, UTXOs or other rails may exist outside the wallet lifecycle; table settlement itself must use the authorized protocol path.

12. DISCONNECTION/REMOVAL

Disconnection, REMOVED, or SEAT_RELEASED states do not themselves authorize money movement. Any financial

consequence must pass through the appropriate authorization path. MSE does not infer financial entitlement from connection state.

13. SECURITY

Authorization integrity, replay protection, duplicate-settlement prevention, asset/network validation, destination and amount binding, and preservation of settlement evidence are mandatory. Timeout or uncertain confirmation must be distinguishable from confirmed settlement.

14. EVENTS AND EVIDENCE

MSE consumes authorized settlement instructions and produces settlement status/evidence. Exact event names belong to the protocol event registry and must not be invented independently by this specification. Evidence should correlate authorization, operation ID, execution attempt, external transaction/equivalent reference, and final status.

15. VERSIONING AND DOCUMENTATION

Documentation records the specification and its versions; documentation does not authorize financial execution. Interface changes affecting interoperability must be versioned and compatibility rules preserved or explicitly declared breaking.

16. NON-RESPONSIBILITIES

No poker-rule decisions. No card generation/dealing. No membership decisions. No table governance. No TABLE_WALLET_INSTANCE lifecycle authority. No disconnection/removal lifecycle authority. No documentation authority. No independent alteration of authorized economic entitlements.

17. CORRECTIONS APPLIED FROM v1.1

Corrected LCCP to SEQ 12 / PREV 11 / NEXT 13. Separated authorization from execution. Preserved Engine 09 wallet lifecycle authority. Separated Engine 10 disconnection/removal from financial authorization. Separated asset/network/rail/L2 concepts. Added idempotency, replay protection, failure/unknown states, evidence, modular interface requirements, and clarified documentation boundaries. Removed the over-broad universal wallet source/destination claim.

18. AUDIT STATUS
